

# Systematic determination of genetic network architecture

Saeed Tavazoie, Jason D. Hughes, Michael J. Cambell, Raymond J. Cho,  
and George M. Church  
Nature Genetics 22: 281-285.

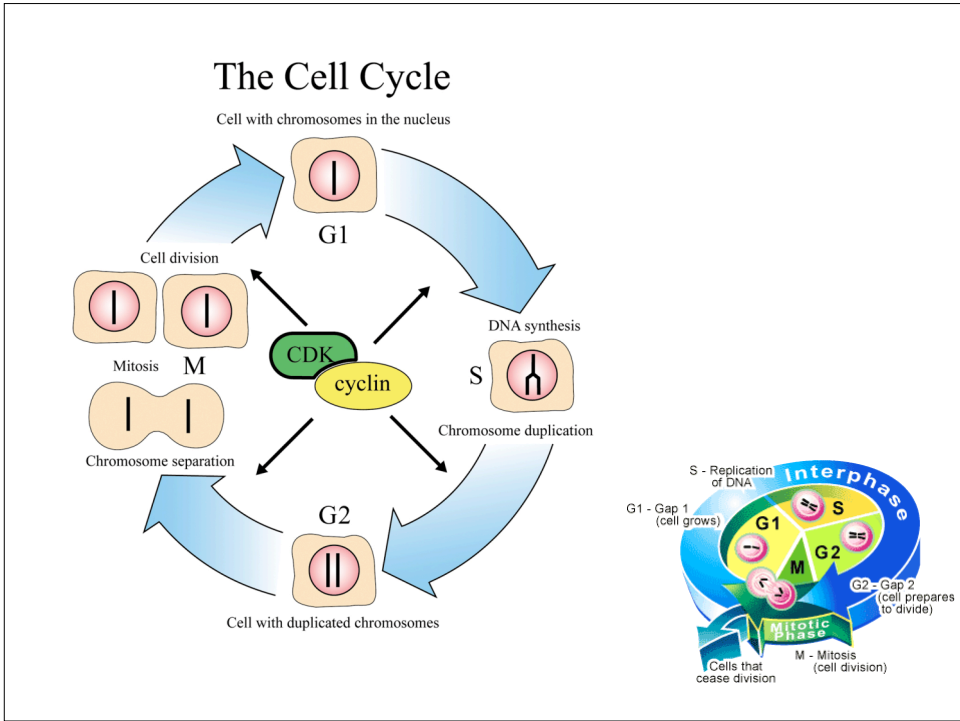

Identification of transcriptional regulatory networks  
from whole-genome mRNA expression data

Goals:

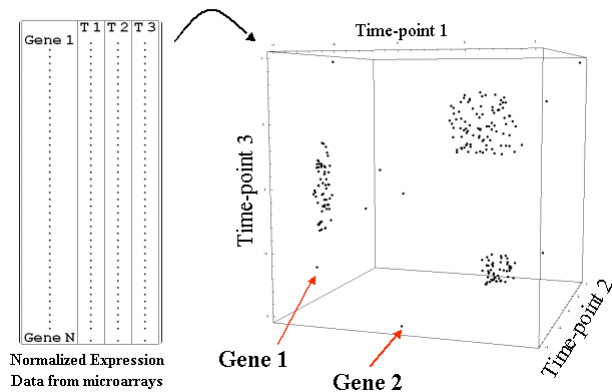

1. Recapitulate the structure of known networks without *a priori* knowledge of their biology.
2. Identify new components of the network and characterize their significance.

Approaches:

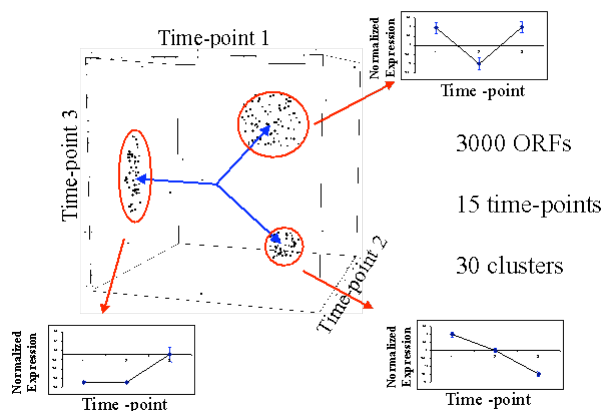

1. Identify **intrinsic mRNA expression patterns** within whole-genome transcriptional profiles.
2. Identify **intrinsic DNA sequence patterns** which are specific to each expression pattern.

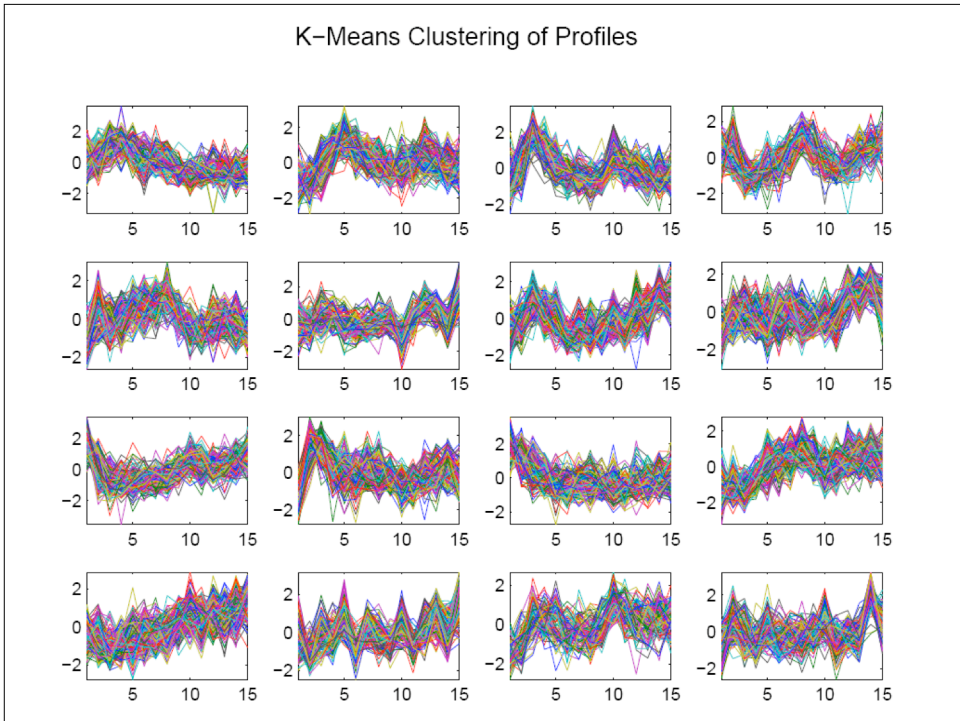

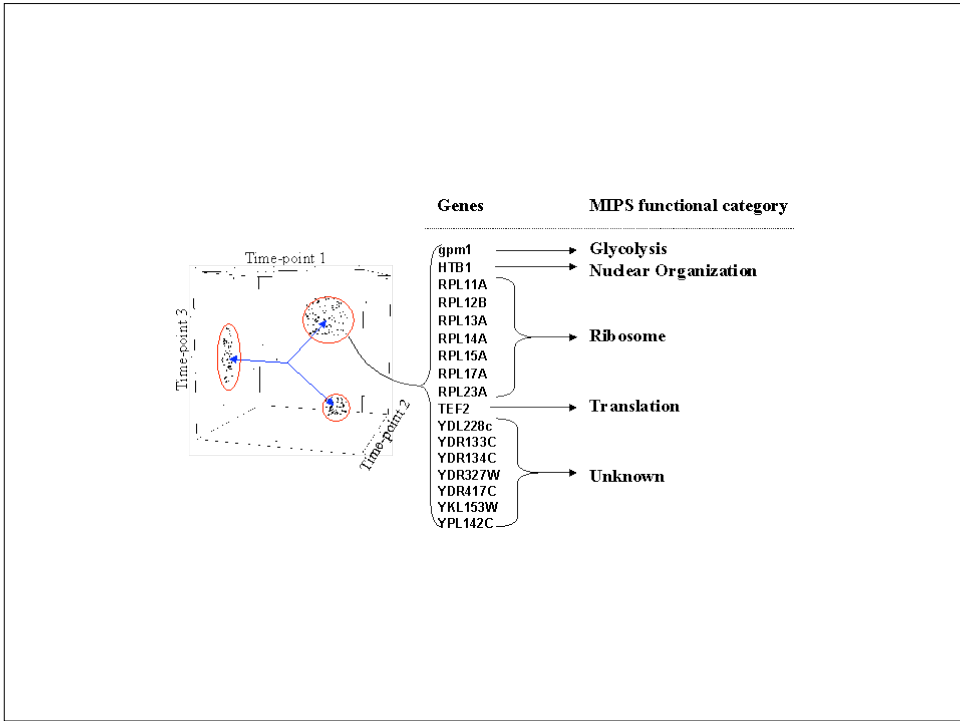

### Representation of expression data

### Identifying prevalent expression patterns (clusters)

## Cell cycle gene expression

3000 genes, 15 time points, (roughly 10 mins interval)

## From expression patterns to DNA sequence patterns

Replication & DNA synthesis (2)

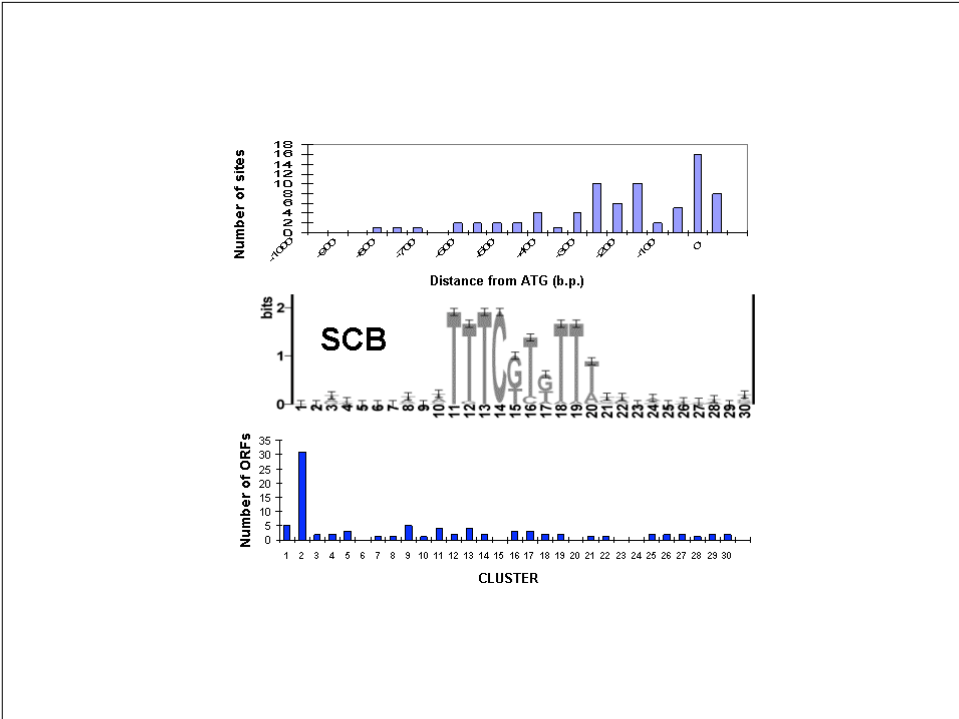

N = 186

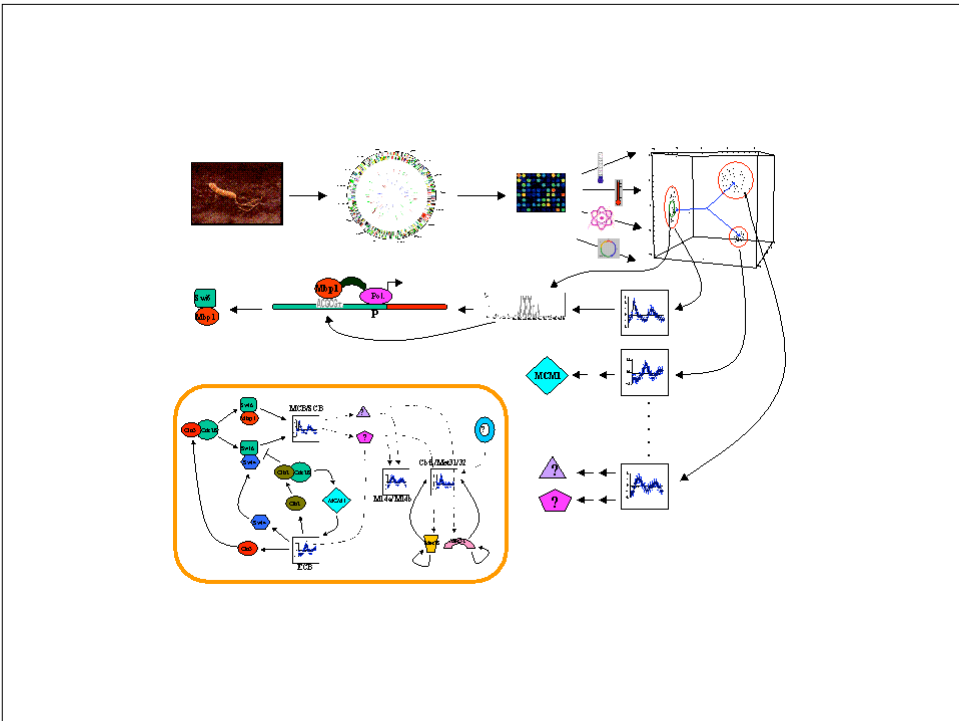

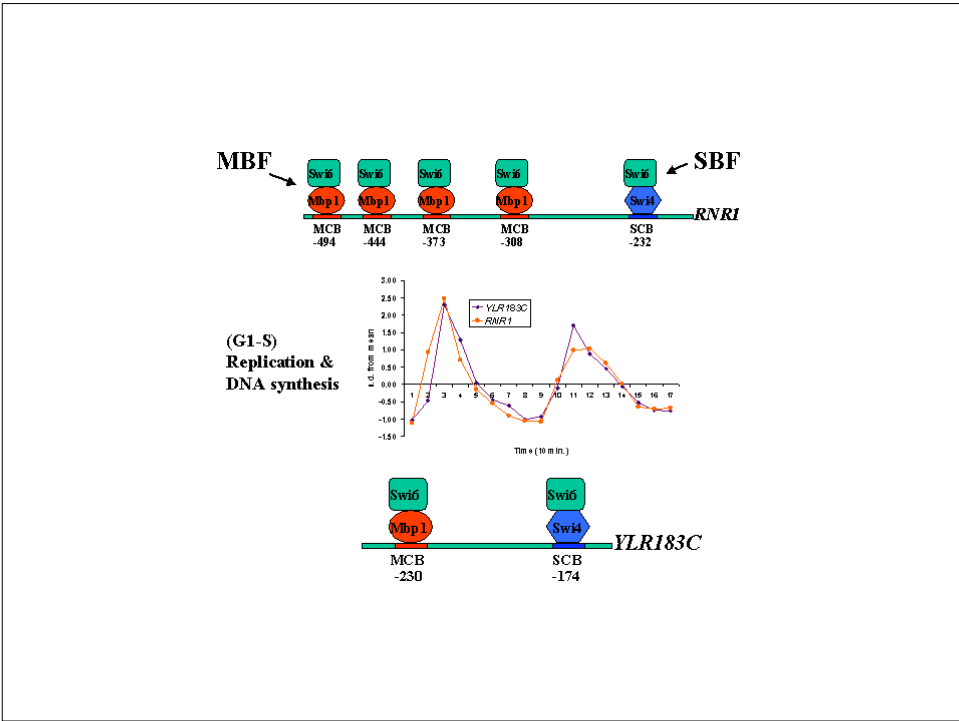

MFS Functional category (total CRFs)	CRFs within functional category (k)	P-value -Log <sub>10</sub>
DNA synthesis and replication (82)	23	16
Cell cycle control and mitosis (312)	30	8
Recombination and DNA repair (84)	11	5
Nuclear organization (720)	40	4

Replication & DNA synthesis (2)

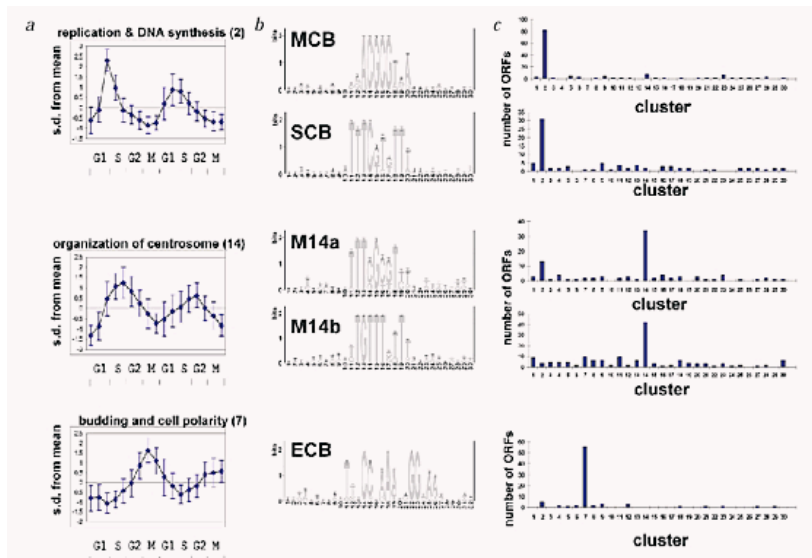

# Method

- Used microarray data by Cho et al. 1998 that consisted of expression data for 6000 genes at 15 time points during two *S. cerevisiae* mitotic cell cycles.
- Analyzed 3000 “most variable ORFs” and normalized data by subtracting the mean expression level value across all time points for each gene.

$$Y_{ij} = \frac{X_{ij} - \langle X_i \rangle}{\left[ \frac{1}{15} \sum_{j=1}^{15} (X_{ij} - \langle X_i \rangle)^2 \right]^{1/2}}$$

- Clustered genes by expression pattern using Euclidean distance metric values in the k-means algorithm

Used AlignACE to align 600bp upstream regions in order to determined common nucleotide motifs.

## Results

- Found 18 motifs in 12 different clusters
  - Seven characterized transcription factor binding sites that are known to regulate many of the genes in their respective cluster.
- Clusters with known regulons have cis-regulatory elements emerged as the highest scoring motif in every case.
  - examples include MCB box and SCB cell-cycle box.
- Motifs that have not been previously described demonstrate strong correlation with clusters that are enrichment for genes with specific functions.
  - Cluster 3 motifs M3a and M3b and their association with RNA and translation related genes within and outside of cluster 3.
- “Half of the 30 clusters were significantly enriched for functional categories or had significant motifs.”
